Chapter 1

Introduction

Agebraic wheels are structures generalising a commutative semiring, attempting to make sense of 'division' by zero.

Loosely speaking, given a semiring R and it's associated monoids, one may extend the semiring in a variety of well-known ways. Considering an additive inverse extends a commutative semiring, to a structure with a given name: a commutative ring, and attempting the same succesfully for the multiplicative monoid yields a field.

The idea of a wheel, is to extend a commutative semiring by introducing a new unary operation $/$, to then have $a \cdot /b$ agree with $a * b^{-1}$.
